Refer to this manual for information on using the software.

If you are having difficulty connecting online and your Internet connection is behind a router using NAT (Network Address Translation), you may need to configure your router settings to allow incoming traffic. However, for the purposes of this document, we will focus on the technical aspects of routing and software installation.

Routing is a critical component of network communication. It involves the process of selecting the best path for data packets to travel from a source to a destination. Routing algorithms are used to determine the most efficient and reliable path for data packets to travel through a network.

For example, the Vehicle Routing Problem (VRP) has been widely studied from a technical point of view for more than 50 years. Schmid et al. (69) and reported a distance reduction of about 23% with respect to manually designed routes of the company. The router selects the logical path across a set of ATN sub-networks that can exist between any two end systems. This involves a manually-configured routing entry with three items: i) destination IP, ii) network mask, and iii) gateway IP.

Surveys and metaheuristics for rich vehicle routing problems are also important in optimizing routes. These include methods such as matheuristics for the order batching and sequencing in manual order picking systems.

The SON (Schmidt's Original Nabendynamo) axle has two male spade connectors. In the photo below you can see one female. A routing algorithm is applied to each batch to know the time that a worker will arrive at a location.

The OBSP has been recently studied in Henn and Schmid (2013), by using a Metaheuristics for the order batching problem in manual order picking systems.
